3 Train a classification model

[122]:
```
# In this project predicting the probability of a flight will deplay, model will␣
↪be a binary classification model that predicts
# whether a flight will arrive on-time or late ("binary" because there are only␣
↪two possible outputs).
# Use RandomForestClassifier which fits multiple decision trees to the data and␣
↪uses averaging to boost the overall accuracy and limit overfitting.
from sklearn.ensemble import RandomForestClassifier
```

[123]:
```
from sklearn.metrics import mean_absolute_error
def get_mae(max_leaf_nodes, n_estimators, train_x, test_x, train_y, test_y):
    model = RandomForestClassifier(max_leaf_nodes=max_leaf_nodes,␣
↪n_estimators=n_estimators, random_state=3)
    model.fit(train_x, train_y)
    preds_val = model.predict(test_x)
    mae = mean_absolute_error(test_y, preds_val)
    return(mae)
```

[131]:
```
# compare MAE with differing values of max_leaf_nodes
scores = {leaf_size: get_mae(leaf_size, 30, train_x, test_x, train_y, test_y)␣
↪for leaf_size in [100, 500, 1000, 2000, 2500, 5000, 10000, 50000]}
```

[132]:
```
best_tree_size = min(scores, key=scores.get)
print(best_tree_size)
```

```
10000
```

[133]:
```
# 'n_estimators' is the number of trees in the forest
model = RandomForestClassifier(random_state=3, max_leaf_nodes=best_tree_size)
model.fit(train_x, train_y)
```

```
/home/nbuser/anaconda3_501/lib/python3.6/site-
packages/sklearn/ensemble/forest.py:246: FutureWarning: The default value of
n_estimators will change from 10 in version 0.20 to 100 in 0.22.
  "10 in version 0.20 to 100 in 0.22.", FutureWarning)
```

[133]:
```
RandomForestClassifier(bootstrap=True, class_weight=None, criterion='gini',
            max_depth=None, max_features='auto', max_leaf_nodes=10000,
            min_impurity_decrease=0.0, min_impurity_split=None,
```

```
                   min_samples_leaf=1, min_samples_split=2,
                   min_weight_fraction_leaf=0.0, n_estimators=10, n_jobs=None,
                   oob_score=False, random_state=3, verbose=0, warm_start=False)
```

[134]:
```
predicted = model.predict(test_x)
model.score(test_x, test_y)
```

[134]: 0.8162402530297811

[135]:
```
# One of the best overall measures for a binary classification model is Area␣
 ↪Under Receiver Operating Characteristic Curve
# (sometimes referred to as "ROC AUC"), which essentially quantifies how often␣
 ↪the model will make a correct prediction
# regardless of the outcome.
# Compute an ROC AUC score for the model

#from sklearn.metrics import roc_auc_score
probabilities = model.predict_proba(test_x)
```

[136]:
```
roc_auc_score(test_y, probabilities[:, 1])
```

[136]: 0.7486295016551348

[137]:
```
# The output from the score method reflects how many of the items in the test␣
 ↪set the model predicted correctly.
# This score is skewed by the fact that the dataset the model was trained and␣
 ↪tested with contains
# many more rows representing on-time arrivals than rows representing late␣
 ↪arrivals.
# Because of this imbalance in the data, it's more likely to be correct if you␣
 ↪predict that a flight will be on time than if you predict that a flight will␣
 ↪be late.
# ROC AUC takes this into account and provides a more accurate indication of how␣
 ↪likely it is that a prediction of on-time or late will be correct.
```

4 Confusion Matrix

[138]:
```
# The confusion matrix quantifies the number of times each answer
# was classified correctly or incorrectly. Specifically, it quantifies the
# number of false positives, false negatives, true positives, and true negatives.
```

[139]:
```
from sklearn.metrics import confusion_matrix
confusion_matrix(test_y, predicted)
```

[139]:
```
array([[24185,   715],
       [ 5153,  1880]])
```

5 Precison and Recall

[140]:
